# 1 Story/Realistic Problem Scenario

*[story like statement of some CP problems]*

## 1.1 Problem

There are two arrays each of size  $n$ ,  $a$  and  $b$  consisting of the first  $n$  positive integers each exactly once, that is, they are permutations.

The task is to find the minimum time required to make both the arrays empty. The following two types of operations can be performed any number of times each taking 1 second:

- In the first operation, you are allowed to rotate the first array clockwise.
- In the second operation, when the first element of both the arrays is the same, they are removed from both the arrays and the process continues.

### Input format:

- The first line contains an integer  $n$ , denoting the size of the array.
- The second line contains the elements of array  $a$ .
- The third line contains the elements of array  $b$ .

### Output format:

Print the total time taken required to empty both the array.

### Constraints:

$$1 \leq n \leq 100$$

### Sample Input:

```
3
1 3 2
2 3 1
```

### Sample Output:

```
6
```

## 2 Basic Understanding of Queues and Deques

### 2.1 Queues

A queue is a FIFO (First-In,First-Out) data structure in which the element that is inserted first is the first one to be taken out. The elements in a queue are added at one end called the REAR and removed from the other end called the FRONT. Queues can be implemented by using either arrays or linked lists.

### 2.1.1 Types of Queues

A queue data structure can be classified into the following types:

- Circular Queue
- Deque
- Priority Queue
- Multiple Queue

## 2.2 Deques

A deque is a list in which the elements can be inserted or deleted at either end. It is also known as a *head-tail linked list* because elements can be added to or removed from either the front(head) or the back(tail) end. But no element can be added and deleted from the middle. In a computer's memory a deque is implemented using either a

- circular array  
or
- circular doubly linked list

The elements in a deque extend from the LEFT end to the RIGHT end and since it is circular, `Dequeue[N-1]` is followed by `Dequeue[0]`.

## 3 Operations Supported

### 3.1 Queues

Some of the basic operations for Queue in Data Structure are:

- **enqueue()** – Insertion of elements to the queue.
- **dequeue()** – Removal of elements from the queue.
- **peek() or front()** - Acquires the data element available at the front node of the queue without deleting it.
- **rear()** – This operation returns the element at the rear end without removing it.
- **isFull()** – Validates if the queue is full.
- **isEmpty()** – Checks if the queue is empty.
- **size()** - This operation returns the size of the queue i.e. the total number of elements it contains.

### 3.1.1 enqueue():

Inserts an element at the end of the queue i.e. at the rear end.

The following steps should be taken to enqueue (insert) data into a queue:

- Check if the queue is full.
- If the queue is full, return overflow error and exit.
- If the queue is not full, increment the rear pointer to point to the next empty space.
- Add the data element to the queue location, where the rear is pointing.
- return success.

```
1 void queueEnqueue(int data)
2 {
3     // Check queue is full or not
4     if (capacity == rear) {
5         printf("\nQueue is full\n");
6         return;
7     }
8
9     // Insert element at the rear
10    else {
11        queue[rear] = data;
12        rear++;
13    }
14    return;
15 }
```

### 3.1.2 dequeue():

This operation removes and returns an element that is at the front end of the queue.

The following steps are taken to perform the dequeue operation:

- Check if the queue is empty.
- If the queue is empty, return the underflow error and exit.
- If the queue is not empty, access the data where the front is pointing.
- Increment the front pointer to point to the next available data element.
- The Return success.

```

1  void queueDequeue()
2  {
3      // If queue is empty
4      if (front == rear) {
5          printf("\nQueue is empty\n");
6          return;
7      }
8
9      // Shift all the elements from index 2
10     // till rear to the left by one
11     else {
12         for (int i = 0; i < rear - 1; i++) {
13             queue[i] = queue[i + 1];
14         }
15
16         // decrement rear
17         rear--;
18     }
19     return;
20 }

```

### 3.1.3 front():

This operation returns the element at the front end without removing it.

The following steps are taken to perform the front operation:

- If the queue is empty return the most minimum value.
- otherwise, return the front value.

```

1  int front(Queue* queue)
2  {
3      if (isempty(queue))
4          return INT_MIN;
5      return queue->arr[queue->front];
6  }

```

### 3.1.4 rear():

This operation returns the element at the rear end without removing it.

The following steps are taken to perform the rear operation:

- If the queue is empty return the most minimum value.
- otherwise, return the rear value.

```

1      int rear(Queue* queue)
2  {
3      if (isEmpty(queue))
4          return INT_MIN;
5      return queue->arr[queue->rear];
6  }

```

### 3.1.5 isEmpty():

This operation returns a boolean value that indicates whether the queue is empty or not.

The following steps are taken to perform the Empty operation:

- check if front value is equal to -1 or not, if yes then return true means queue is empty.
- Otherwise return false, means queue is not empty

```

1      // This function will check whether
2  // the queue is empty or not:
3  bool isEmpty()
4  {
5      if (front == -1)
6          return true;
7      else
8          return false;
9  }

```

### 3.1.6 isFull():

This operation returns a boolean value that indicates whether the queue is full or not.

The following steps are taken to perform the isFull() operation:

- Check if front value is equal to zero and rear is equal to the capacity of queue if yes then return true.
- otherwise return false

```

1      // This function will check
2  // whether the queue is full or not.
3  bool isFull()
4  {
5      if (front == 0 && rear == MAX_SIZE - 1) {
6          return true;

```

```

7     }
8     return false;
9 }

```

### 3.1.7 size():

This operation returns the size of the queue i.e. the total number of elements it contains.

```

1 // CPP program to illustrate
2 // Implementation of size() function
3 #include <iostream>
4 #include <queue>
5 using namespace std;
6
7 int main()
8 {
9     int sum = 0;
10    queue<int> myqueue;
11    myqueue.push(1);
12    myqueue.push(8);
13    myqueue.push(3);
14    myqueue.push(6);
15    myqueue.push(2);
16
17    // Queue becomes 1, 8, 3, 6, 2
18
19    cout << myqueue.size();
20
21    return 0;
22 }

```

## 3.2 Deques

There are two variants a deque. They include-

- **Input restricted deque:** Here insertions can only be done at one of the ends. While deletions can be done from both ends.
- **Output restricted deque:** Here deletions can be done only at one of the ends. While insertions can be done on both ends.

In a deque in data structure we can perform the following operations:

- Insertion at front
- Insertion at rear

- Deletion at front
- Deletion at rear

Before performing the following operations, we must follow the below steps :

- Take a deque(array) of size  $n$
- Set two pointers variables  $\text{front} = -1$  and  $\text{rear} = 0$  at the first position.

### **3.2.1 Insertion at front**

1. Initially, we will check the position of the front variable in our array
2. In case, the front variable is less than 1 ( $\text{front} < 1$ ), we will reinitialize the front as the last index of the array ( $\text{front} = n-1$ ).
3. Otherwise, we will decrease the front by 1.
4. Add the new key for example 5 here into our array at the index front - array[front].
5. Every time we insert a new element inside the deque the size increases by 1.

### **3.2.2 Insertion at rear**

1. At first, we need to check whether the deque in data structure is full or not.
2. If the deque data structure is full, we have to reinitialize the rear with 0 ( $\text{rear} = 0$ ).
3. Else increase the rear by 1.
4. Add the new key for example 5 here into our array at the index rear - array[rear].
5. Every time we insert a new element inside the deque the size increases by 1.

### **3.2.3 Deletion at front**

1. At first, we need to check whether the deque in data structure is empty or not.
2. If the deque data structure is empty i.e.  $\text{front} = -1$ , we cannot perform the deletion process and it will throw an error of underflow condition.

3. If the deque data structure contains only one element i.e.  $\text{front} = \text{rear}$ , set  $\text{front} = -1$  and  $\text{rear} = -1$ .
4. Else if the front is at the last index i.e.  $\text{front} = n - 1$ , we point the front to the starting index of the deque data structure i.e.  $\text{front} = 0$ .
5. If none of the cases satisfy we simply increment our front by 1,  $\text{front} = \text{front} + 1$ .
6. Every time we delete any element from the deque data structure the size decreases by 1.

#### 3.2.4 Deletion at rear

1. At first, we need to check whether the deque data structure is empty or not.
2. If the deque data structure is empty i.e.  $\text{front} = -1$ , we cannot perform the deletion process and it will throw an error of underflow condition.
3. If the deque data structure contains only one element i.e.  $\text{front} = \text{rear}$ , set  $\text{front} = -1$  and  $\text{rear} = -1$ .
4. Else if the rear is at the starting index of the deque i.e.  $\text{rear} = 0$ , point the rear to the last index of the deque data structure i.e.  $\text{rear} = n-1$ .
5. If none of the cases satisfy we simply decrement our rear by 1,  $\text{rear} = \text{rear} - 1$ .
6. Every time we delete any element from the deque the size decreases by 1.

Here's an implementation of basic deque operations:

```

1      // Deque implementation in C++
2
3      #include <iostream>
4      using namespace std;
5
6      #define MAX 10
7
8      class Deque {
9      int arr[MAX];
10     int front;
11     int rear;
12     int size;
13
14     public:
15     Deque(int size) {
16         front = -1;

```

```

17     rear = 0;
18     this->size = size;
19 }
20
21 void insertfront(int key);
22 void insertrear(int key);
23 void deletefront();
24 void deleterear();
25 bool isFull();
26 bool isEmpty();
27 int getFront();
28 int getRear();
29 };
30
31 bool Deque::isFull() {
32     return ((front == 0 && rear == size - 1) ||
33            front == rear + 1);
34 }
35
36 bool Deque::isEmpty() {
37     return (front == -1);
38 }
39
40 void Deque::insertfront(int key) {
41     if (isFull()) {
42         cout << "Overflow\n"
43              << endl;
44         return;
45     }
46
47     if (front == -1) {
48         front = 0;
49         rear = 0;
50     }
51
52     else if (front == 0)
53         front = size - 1;
54
55     else
56         front = front - 1;
57
58     arr[front] = key;
59 }
60
61 void Deque ::insertrear(int key) {
62     if (isFull()) {

```

```

63     cout << " Overflow\n " << endl;
64     return;
65 }
66
67 if (front == -1) {
68     front = 0;
69     rear = 0;
70 }
71
72 else if (rear == size - 1)
73     rear = 0;
74
75 else
76     rear = rear + 1;
77
78 arr[rear] = key;
79 }
80
81 void Deque ::deletefront() {
82     if (isEmpty()) {
83         cout << "Queue Underflow\n"
84             << endl;
85         return;
86     }
87
88     if (front == rear) {
89         front = -1;
90         rear = -1;
91     } else if (front == size - 1)
92         front = 0;
93
94     else
95         front = front + 1;
96 }
97
98 void Deque::deleterear() {
99     if (isEmpty()) {
100         cout << " Underflow\n"
101             << endl;
102         return;
103     }
104
105     if (front == rear) {
106         front = -1;
107         rear = -1;
108     } else if (rear == 0)

```

```

109     rear = size - 1;
110     else
111         rear = rear - 1;
112 }
113
114 int Deque::getFront() {
115     if (isEmpty()) {
116         cout << " Underflow\n"
117             << endl;
118         return -1;
119     }
120     return arr[front];
121 }
122
123 int Deque::getRear() {
124     if (isEmpty() || rear < 0) {
125         cout << " Underflow\n"
126             << endl;
127         return -1;
128     }
129     return arr[rear];
130 }
131
132 int main() {
133     Deque dq(4);
134
135     cout << "insert element at rear end \n";
136     dq.insertrear(5);
137     dq.insertrear(11);
138
139     cout << "rear element: "
140         << dq.getRear() << endl;
141
142     dq.deleterear();
143     cout << "after deletion of the rear element, the new
144         rear element: " << dq.getRear() << endl;
145
146     cout << "insert element at front end \n";
147
148     dq.insertfront(8);
149
150     cout << "front element: " << dq.getFront() << endl;
151
152     dq.deletefront();
153     cout << "after deletion of front element new front

```

```

154         element: " << dq.getFront() << endl;
    }

```

## 4 The Solution

### 4.1 The intuition behind the solution

This problem can be easily solved using well known data structure that is queue. Firstly insert all the elements of the first array in the push queue Q. Now, start iterating through the queue from the front, and check if the top element of the queue is similar to the second array or not, if they are same then pop the first element and continue the process until the queue gets empty else remove the top element and push it at the back, repeat this process further.

- Perform operation 1 to make a = 3, 2, 1
- Perform operation 1 to make a = 2, 1, 3
- Now perform operation 2 to make a = 1, 3 and b = 3, 1
- Perform operation 1 to make a = 3, 1
- Now perform operation 2 to make a = 1 and b = 1
- Now perform operation 2 to make a = {} and b = {}

```

1  #include <iostream>
2  #include <queue>
3
4  using namespace std;
5
6  int main()
7  {
8      int n, Num; // n is the size of the array, Num stores
9                  // each input integer
10     cin >> n;
11
12     queue<int> Qa, Qb; // one for a array and one for b
13                        // array
14     for (int i = 0; i < n; i++)
15     {
16         cin >> Num;
17         Qa.push(Num); // reads n Num integers for Qa and
18                       // pushes them into Qa
19     }

```

```

18     for (int i = 0; i < n; i++)
19     {
20         cin >> Num;
21         Qb.push(Num); //same as Qa
22     }
23
24     int TimeNeeded = 0; //the required time
25     while (!Qa.empty() && !Qb.empty()) //loop continues
26         until both queues are empty
27     {
28         if (Qa.front() == Qb.front())
29         {
30             Qa.pop(); //if both of the front elements
31             //are equal then they are popped as per
32             //the operation 2.
33             Qb.pop();
34             TimeNeeded++;
35         }
36         else
37         {
38             int FrontElement_Qa = Qa.front(); //stores
39             //the front element of Qa in a temporary
40             //variable
41             Qa.pop(); //pops the first element
42             Qa.push(FrontElement_Qa); //and then pushes
43             //it in the back of Qa. That way it
44             //rotates clockwise.
45             TimeNeeded++;
46         }
47     }
48
49     cout << TimeNeeded << endl;
50     return 0;
51 }

```

## 4.2 Complexity Analysis

### 4.2.1 Time Complexity

- Reading input involves iterating through both arrays a and b, which has a time complexity of  $O(n)$  due to two separate loops.
- Enqueuing the elements into the queues (push()):  $O(n)$  for each queue (it's  $2 \cdot O(n)$  for two queues which is still  $O(n)$ ).

- Dequeueing and checking elements while both queues are not empty: In the worst case, the while loop will run for a maximum of  $2*n$  times (once per each element in both arrays).
  - Checking front elements (front()):  $O(1)$
  - Removing elements from the queues (pop()):  $O(1)$
  - Pushing elements to the back of queue Qa (push()):  $O(1)$

So, the total complexity of operations inside the loop is  $2n*O(1)$ , which is  $O(n)$ .

#### 4.2.2 Space Complexity

- **Queue Space:** Two queues Qa and Qb are created to store the elements of arrays a and b respectively. Each queue stores 'n' elements. Therefore, the space complexity for the queues is  $O(n+n)$ , which is  $O(n)$ .
- **Additional Space:** Apart from the queues, the solution uses a few integer variables (n, Num, TimeNeeded, i) which are not dependent on the input size and are constant. Hence, they don't significantly contribute to the space complexity.

Therefore, the overall space complexity of this solution is  $O(n)$  due to the queues storing the elements from both arrays.

## 7 Conclusion Comments

Basically [queues](#) and [dequeues](#) are fundamental data structures used in computer science and programming to manage elements in an ordered manner. They both have distinct characteristics and optimal use cases.

Both structures have their strengths: [queues](#) excel in maintaining order and managing processes, while [dequeues](#) offer versatility and efficiency in handling elements from both ends. Understanding their characteristics and choosing the right one for a specific task or problem is crucial for efficient algorithm design and implementation.

[Queues](#) can be used in-

- Managing requests on a single shared resource such as CPU scheduling and disk scheduling.
- Handling hardware or real-time systems interrupts.
- Handling website traffic.
- Routers and switches in networking.
- Maintaining the playlist in media players.

[Dequeues](#) can be used in-

- Implementing Stack
- Double-ended priority queue
- Undo operations in Editors

Queues and dequeues are versatile data structures, but there are scenarios where they might not be the optimal choice or might not fit the requirements efficiently.

- **Random Access:** Queues and dequeues are designed for sequential access and efficient insertion/deletion at specific ends. If frequent random access to elements by index is a primary requirement, arrays might be more suitable.
- **Large-Scale Data Sorting:** Queues are not typically used for large-scale sorting due to inefficiencies in comparison-based sorting algorithms.
- **Real-Time Data Processing:** In scenarios requiring real-time data processing, the overhead involved in managing queues or dequeues might not be suitable.
- **Complex-Graph Algorithms:** While queues are fundamental for algorithms like BFS, more complex graph algorithms might require additional data structures or specialized implementations to optimize memory usage or improve runtime efficiency.
